ACKNOWLEDGEMENTS

A project of this magnitude and nature requires kind co-operation and support from many, for successful completion. We wish to express our sincere thanks to all those who helped us in the completion of this project.

We would like to express our deep gratitude to Our Beloved Secretary and Correspondent, **Dr.P.Chinnadurai M.A., Ph.D.,** for his motivation which inspired us a lot in completing this project work. We also offer our sincere thanks to our dynamic directors **Mrs. C.Vijayarajeswari, Dr.C.Sakthi Kumar M.E., Ph.D.,** and **Dr. Saranya Sree Sakthi Kumar B.E., M.B.A, Ph.D.,** for providing us with the necessary facilities and support needed to complete this project.

We also express our appreciation and gratefulness to our principal **Dr. K. Mani M.E., Ph.D.,**who never failed to motivate and encourage us in all our initiatives and also helped us in the completion of the project.

We would like to extend our gratitude and thanks to our Head of the Department **Dr.S.Rajakumar M.E., Ph.D.,** for his valuable suggestions and continuous encouragement throughout the completion of our project.

Our utmost gratitude and thanks to our project supervisor **Dr.R.MARY VICTORIA**, **M.E, Ph.D.,** Assisstant Professor, Department of Electronics and Communication Engineering for her constant guidance, motivation, and valuable suggestions throughout the course of this project work and for helping us to complete this project work on time.

We are grateful to our beloved parents for providing us with all the support and the opportunities to complete this project work. We also express our sincere thanks to all our friends and family members for their endless support.

ABSTRACT

The landscape of industrial automation continues to evolve rapidly, with vertical material handling emerging as a critical operational domain that directly influences manufacturing efficiency and throughput. Traditional hydraulic scissor lifts, while proven workhorses in industrial environments, exhibit inherent limitations that increasingly conflict with the demands of modern smart manufacturing facilities. These constraints include relatively slow actuation velocities, substantial maintenance overhead attributable to hydraulic fluid management and seal degradation, environmental concerns associated with potential oil contamination, and challenges in achieving precise positional control.

This project presents the comprehensive design, development, and implementation of an **Automatic Pantograph Lifter** that leverages innovative **Zip Chain Technology** as its primary actuation mechanism, governed by a **Delta Programmable Logic Controller (PLC)**. The proposed system fundamentally reimagines the vertical transfer paradigm by replacing conventional hydraulic cylinders with an electrically-driven Zip Chain Actuator—a sophisticated mechanism wherein two flexible roller chains interlock or "zip" together to form a structurally rigid column capable of transmitting substantial axial forces for load elevation.

The control architecture integrates **Inductive Proximity Sensors** for accurate position feedback, **Electromagnetic Relays** for motor switching operations, and a **Switched Mode Power Supply (SMPS)** for efficient power distribution across system components. This configuration delivers lifting velocities approaching 60 meters per minute—representing an order-of-magnitude improvement over hydraulic counterparts—while simultaneously achieving millimeter-level positioning accuracy through digital control methodologies.

The elimination of hydraulic fluid renders this system an environmentally responsible solution, directly supporting **Sustainable Development Goal**

9 (Industry, Innovation, and Infrastructure) through technological advancement, **SDG 12** (Responsible Consumption and Production) via hazardous waste elimination, and **SDG 7** (Affordable and Clean Energy) through improved energy efficiency. The resultant system constitutes a compact, high-velocity, and contamination-free vertical transfer unit optimally suited for deployment in contemporary smart factory environments operating under Industry 4.0 paradigms.

Keywords: Zip Chain Actuator, Pantograph Lifter, Delta PLC, Inductive Proximity Sensor, Industrial Automation, Sustainable Manufacturing

CHAPTER 1: INTRODUCTION

1.1 Background and Context

The contemporary industrial landscape is characterized by an unprecedented emphasis on operational efficiency, production velocity, and sustainable manufacturing practices. Within this context, material handling operations constitute a fundamental pillar supporting virtually every manufacturing and logistics enterprise. The movement of raw materials, work-in-progress components, and finished goods through production facilities demands sophisticated mechanical systems capable of meeting increasingly stringent performance requirements.

Vertical material handling, specifically the elevation and lowering of loads between different height levels, represents a particularly critical operational domain. Manufacturing facilities, warehouses, distribution centers, and assembly plants routinely require the transfer of materials between floor levels, loading docks, mezzanines, and elevated workstations. The equipment employed for these vertical transfer operations directly influences production throughput, worker safety, and overall operational economics.

The emergence of Industry 4.0—the fourth industrial revolution characterized by cyber-physical systems, the Internet of Things (IoT), cloud computing, and cognitive computing—has fundamentally altered expectations for industrial equipment. Modern smart factories demand machinery that operates with high precision, communicates its status in real-time, consumes energy efficiently, and requires minimal human intervention. Traditional material handling equipment, designed for an earlier era of manufacturing, often struggles to meet these evolved requirements.

The pantograph mechanism, named after its resemblance to the pantograph devices historically used for copying drawings, has long served as an effective means of achieving vertical displacement. The scissoring action of interconnected arms provides mechanical advantage while maintaining a compact footprint when retracted. However, the actuation systems driving these pantograph mechanisms have historically imposed limitations that increasingly conflict with modern manufacturing demands.

This project emerges from the recognition that fundamental innovation in pantograph actuation technology offers substantial opportunities for performance improvement. By replacing conventional hydraulic actuation with an advanced electromechanical alternative—specifically Zip Chain Technology—this work aims to demonstrate that significant gains in speed, precision, and environmental performance are achievable without sacrificing load capacity or reliability.

1.2 Evolution of Material Handling Systems

The history of mechanical lifting devices extends back millennia, with early civilizations developing rudimentary cranes, hoists, and lifting platforms to facilitate construction and commerce. The ancient Egyptians employed inclined planes and lever systems to position massive stone blocks during pyramid construction. Greek and Roman engineers advanced crane technology, introducing compound pulley systems that provided substantial mechanical advantage.

The Industrial Revolution of the 18th and 19th centuries catalyzed dramatic advances in lifting technology. The availability of steam power, and subsequently electrical power, enabled the development of powered hoists and elevators that fundamentally transformed building construction, manufacturing, and urban development. The hydraulic elevator, patented by Elisha Otis in the 1850s, represented a particularly significant innovation by incorporating a safety mechanism that prevented catastrophic falls.

The 20th century witnessed the proliferation of hydraulic systems across industrial applications. The advantages of hydraulic power—including high force density, smooth motion control, and the ability to transmit power through flexible hoses to remote actuators—made hydraulic systems the dominant choice for heavy-duty lifting applications. Hydraulic scissor lifts, forklifts, and aerial work platforms became ubiquitous in manufacturing, construction, and logistics operations.

However, the late 20th and early 21st centuries brought growing awareness of the limitations and environmental implications of hydraulic technology. Concerns regarding hydraulic fluid leakage, disposal requirements, energy inefficiency, and maintenance complexity prompted the exploration of alternative actuation technologies. Electric linear actuators, ball screw drives, and belt-driven systems emerged as competitors to hydraulic actuation in various applications.

The development of Zip Chain Technology represents a particularly innovative contribution to the evolution of linear actuation. By creating a mechanism that transforms flexible chain elements into rigid push-pull columns, this technology achieves the high force capability traditionally associated with hydraulic cylinders while leveraging the simplicity and cleanliness of electric drive systems.

1.3 Problem Statement

Despite their widespread adoption and proven reliability in heavy-duty applications, conventional hydraulic scissor lifts and pantograph mechanisms exhibit several inherent limitations that increasingly conflict with the requirements of modern manufacturing environments:

Speed Limitations: Hydraulic actuation fundamentally depends on the controlled flow of incompressible fluid. The rate of cylinder extension or retraction is directly proportional to the volumetric flow rate of hydraulic fluid, which is constrained by pump capacity, valve flow coefficients, and pressure drop through the hydraulic circuit. Typical hydraulic scissor lifts achieve lifting speeds in the range of 4 to 6 meters per minute—velocities that often constitute bottlenecks in high-throughput production lines. Attempts to increase speed by enlarging pumps and valves result in proportionally larger, more expensive, and more energy-intensive systems.

Positional Accuracy Challenges: Achieving precise positional control with hydraulic systems presents inherent difficulties. Hydraulic fluid, while nominally incompressible, exhibits measurable compressibility under high pressure. This compressibility, combined with the elasticity of hoses and the response characteristics of proportional valves, introduces positioning uncertainties. Furthermore, the phenomenon of hydraulic creep—gradual position drift under sustained load—can compromise accuracy in applications requiring maintained positions. Temperature variations affect fluid viscosity, further complicating consistent positioning performance.

Environmental and Safety Concerns: Hydraulic systems pose environmental risks through potential fluid leakage. Hydraulic fluid escaping from damaged seals, burst hoses, or worn fittings can contaminate floors, products, and the surrounding environment. Many hydraulic fluids are classified as hazardous materials requiring specialized disposal procedures. In food processing, pharmaceutical manufacturing, and cleanroom environments, the contamination risk associated with hydraulic fluid may render such systems entirely unsuitable.

Maintenance Burden: Hydraulic systems demand regular maintenance attention. Fluid levels must be monitored and replenished. Filters require periodic replacement to prevent contamination-induced wear. Seals degrade

over time and require replacement before catastrophic failure. Hoses age and must be inspected and replaced proactively. The cumulative maintenance burden translates to significant operational costs and production downtime.

Energy Inefficiency: Hydraulic systems typically employ continuously running pumps that maintain system pressure even when no lifting action is occurring. This idling operation wastes energy and generates heat that may require additional cooling provisions. The overall energy efficiency of hydraulic systems—considering pump losses, valve losses, and heat generation—typically ranges from 25% to 50%, comparing unfavorably with modern electric drive alternatives.

The convergence of these limitations creates a compelling case for alternative approaches to pantograph actuation. This project addresses this opportunity by developing an automatic pantograph lifter that eliminates hydraulic actuation in favor of Zip Chain Technology controlled by programmable logic.

1.4 Need for the Project

The manufacturing industry's transition toward smart factory paradigms has created urgent requirements for material handling equipment that aligns with Industry 4.0 principles. Several specific needs motivate this project:

Increased Production Velocity: Contemporary manufacturing philosophies, including lean manufacturing and just-in-time production, emphasize the elimination of waste—including the waste of waiting time. Material handling equipment that operates slowly creates queues, extends cycle times, and limits overall production throughput. The need exists for vertical transfer systems capable of operating at velocities that match or exceed the pace of other automated equipment in the production flow.

Precision Requirements: Modern manufacturing processes increasingly demand precise positioning of materials and workpieces. Assembly operations, machining centers, and inspection systems require that materials arrive at exact positions to ensure proper processing. The need exists for lifting systems that can achieve and maintain specified positions with millimeter-level accuracy.

Clean Operation: Many manufacturing sectors impose stringent cleanliness requirements that preclude the use of systems with contamination potential. Food and beverage processing, pharmaceutical manufacturing, semiconductor fabrication, and medical device production all require environments free from oil contamination. The need exists for powerful lifting systems that operate without hydraulic fluid.

Reduced Maintenance: Maintenance activities consume resources, require skilled personnel, and interrupt production operations. Systems requiring frequent attention impose ongoing costs that may exceed initial capital

investments over the equipment's operating life. The need exists for lifting systems that operate reliably with minimal maintenance intervention.

Energy Efficiency: Rising energy costs and growing environmental awareness have elevated energy efficiency to a primary selection criterion for industrial equipment. Systems that consume power only when performing useful work, rather than continuously dissipating energy, align with both economic and sustainability objectives. The need exists for lifting systems that dramatically reduce energy consumption compared to hydraulic alternatives.

Programmable Flexibility: Modern production environments frequently change, with product mixes evolving, process modifications occurring, and continuous improvement initiatives requiring equipment adjustments. Systems that can be reconfigured through software changes, rather than mechanical modifications, offer substantial advantages. The need exists for lifting systems with programmable control that enables easy adaptation to changing requirements.

1.5 Objectives of the Project

This project pursues the following specific objectives:

Primary Objectives:

1. **Design and develop an Automatic Pantograph Lifter** utilizing Zip Chain Technology as the primary actuation mechanism, replacing conventional hydraulic cylinders with an electromechanical alternative.

2. **Implement PLC-based automated control** using a Delta Programmable Logic Controller to govern the lifting and lowering operations with precise timing and position control.

3. **Achieve lifting speeds of 40-60 meters per minute**, representing a ten-fold improvement over typical hydraulic scissor lift performance.

4. **Attain positional accuracy of ±0.1 millimeters** through the integration of inductive proximity sensors and appropriate control logic.

5. **Eliminate hydraulic fluid** from the system entirely, creating a clean, environmentally responsible lifting solution suitable for sensitive manufacturing environments.

Secondary Objectives:

6. **Minimize maintenance requirements** by eliminating wear-prone hydraulic components including seals, filters, and hoses.

7. **Reduce energy consumption** by employing on-demand electric actuation rather than continuous hydraulic pump operation.

8. **Incorporate comprehensive safety features** including limit switches, emergency stop functionality, and overload protection.

9. **Document the design process** thoroughly to facilitate potential commercial development and academic dissemination.

10. **Validate performance through testing** including cycle time measurement, accuracy verification, and comparative analysis against hydraulic alternatives.

1.6 Scope of Work

This project encompasses the following scope of activities:

Included within Scope:

- Comprehensive literature review examining lifting technologies, actuation mechanisms, and control systems
- Detailed analysis of existing hydraulic scissor lift limitations
- Conceptual design of the Zip Chain-based pantograph system
- Selection and specification of all system components
- Mechanical design of the pantograph frame and mounting provisions
- Electrical design including power distribution and control circuits
- PLC program development for automated operation
- Prototype fabrication and assembly
- Testing and performance validation
- Documentation and report preparation

Excluded from Scope:

- Development of custom Zip Chain mechanisms (utilizing commercially available units)
- Large-scale structural analysis requiring finite element methods
- Fatigue life testing requiring extended duration
- Integration with plant-wide manufacturing execution systems
- Regulatory certification for specific industry applications

1.7 Alignment with Sustainable Development Goals

The United Nations Sustainable Development Goals (SDGs), adopted in 2015, establish a shared blueprint for peace and prosperity for people and the planet. This project contributes to the achievement of several SDGs through its technical approach and performance characteristics:

SDG 9: Industry, Innovation, and Infrastructure

SDG 9 calls for building resilient infrastructure, promoting inclusive and sustainable industrialization, and fostering innovation. This project directly advances these objectives by:

- Introducing innovative Zip Chain Technology to the vertical transfer application domain
- Upgrading industrial infrastructure through higher-performance lifting equipment
- Demonstrating the integration of programmable automation for enhanced capability
- Providing a pathway for manufacturing facilities to modernize their material handling operations

The transition from hydraulic to electromechanical actuation represents genuine technological innovation that enhances the efficiency and capability of industrial infrastructure.

SDG 12: Responsible Consumption and Production

SDG 12 promotes sustainable consumption and production patterns. This project supports SDG 12 through:

- Elimination of hydraulic fluid, removing a source of potential environmental contamination
- Reduced material waste through elimination of consumable filters and periodic fluid changes
- Extended equipment life expectancy due to reduced wear mechanisms
- Lower resource consumption through improved energy efficiency

By removing hydraulic oil from the vertical transfer equation, this project directly reduces the chemical burden associated with manufacturing operations.

SDG 7: Affordable and Clean Energy

SDG 7 aims to ensure access to affordable, reliable, sustainable, and modern energy. This project contributes by:

- Dramatically reducing energy consumption compared to hydraulic alternatives
- Eliminating idling energy losses associated with continuous pump operation
- Improving power factor through efficient electric drive systems
- Enabling potential integration with renewable energy sources

The on-demand nature of electric actuation, consuming power only during actual movement, represents a fundamentally more efficient approach to energy utilization.

1.8 Organization of the Report

This project report is organized into seven chapters, each addressing a specific aspect of the work:

Chapter 1: Introduction provides background context, identifies the problem being addressed, states project objectives, defines scope, and establishes connections to sustainable development goals.

Chapter 2: Literature Survey reviews published research and technical literature relevant to lifting mechanisms, chain actuation systems, programmable logic controllers, and sensor technologies.

Chapter 3: Existing System Analysis examines conventional hydraulic scissor lifts in detail, including their operating principles, components, and limitations.

Chapter 4: Proposed System Design presents the complete design of the Zip Chain-based automatic pantograph lifter, including component selection, mechanical design, electrical design, and PLC programming.

Chapter 5: Implementation and Testing describes the prototype fabrication process, assembly procedures, and testing methodology.

Chapter 6: Results and Discussion presents experimental data, analyzes system performance, and compares results against project objectives and existing technology.

Chapter 7: Conclusion and Future Scope summarizes project achievements, identifies contributions, acknowledges limitations, and recommends directions for future development.

CHAPTER 2: LITERATURE SURVEY

2.1 Historical Development of Lifting Mechanisms

The development of mechanical lifting devices represents one of humanity's earliest engineering endeavors. Archaeological evidence suggests that lever-based lifting mechanisms were employed in ancient Mesopotamia as early as 3000 BCE. The shaduf, a counterweighted lever used for irrigation, demonstrated the fundamental mechanical advantage principle that would underpin all subsequent lifting technology.

Ancient Egyptian construction practices, particularly those associated with pyramid building, required the movement of massive stone blocks weighing several tons. While debate continues regarding exact methods, scholarly consensus supports the use of inclined planes, levers, and possibly primitive cranes. The engineering sophistication required to position stones with the precision observed in surviving structures indicates advanced understanding of mechanical principles.

Greek engineers of the classical period, particularly Archimedes, formalized the mathematical principles governing mechanical advantage. The development of compound pulley systems enabled the lifting of loads far exceeding what human or animal power could achieve directly. Vitruvius, the Roman architect and engineer, documented crane designs incorporating treadwheels that allowed workers to develop substantial lifting power through continuous walking motion.

The medieval period saw the proliferation of crane technology across European construction sites. Gothic cathedral construction, with its soaring heights and massive stone elements, drove continued innovation in lifting capability. The introduction of the ratchet mechanism provided a means of preventing uncontrolled load descent, representing an early safety feature.

The Industrial Revolution fundamentally transformed lifting technology through the introduction of powered drives. Steam-powered hoists appeared in mines and factories during the late 18th century. The development of hydraulic power transmission by Joseph Bramah in 1795 established the technological foundation for hydraulic lifting systems that would dominate heavy-duty applications for the following two centuries.

Electric motors, developed in the latter half of the 19th century, provided an alternative power source that would eventually challenge hydraulic dominance in many applications. The clean operation, precise controllability, and ease of power distribution offered by electric drives made them attractive for

applications where these characteristics outweighed hydraulic advantages in force density.

2.2 Advances in Chain-Based Actuation

Chain mechanisms have served industrial applications for centuries, primarily in the transmission of rotary motion and the conveyance of materials. The development of roller chains in the late 19th century, pioneered by Hans Renold, established the fundamental link design that remains standard today. The precision manufacturing of chain components enabled reliable operation at substantial power levels.

The adaptation of chain mechanisms for linear actuation—creating push-pull capability rather than solely tensile force transmission—represented a significant conceptual advancement. Early attempts employed various arrangements of rigid links and pivots, but these systems suffered from complexity and limited stroke length up to 5 Meter lifting length.

The Zip Chain concept, developed and commercialized by Tsubakimoto Chain Company of Japan, introduced a fundamentally different approach. The technology employs two chains that engage with each other through specially designed link profiles. When fed together through a sprocket mechanism, the chains interlock to form a single rigid column capable of transmitting both tensile and compressive forces.

Research published by Tsubakimoto engineers demonstrates that Zip Chain systems can achieve pushing forces comparable to hydraulic cylinders of similar size while operating at significantly higher speeds. The rigid column formed by the interlocked chains exhibits buckling resistance determined by the cross-sectional geometry and material properties, enabling substantial load capacity.

Academic studies examining chain-based actuation have explored various aspects including:

- Dynamic behavior during high-speed operation
- Fatigue life of interlocking elements under cyclic loading
- Optimization of link geometry for maximum rigidity
- Lubrication requirements for sustained operation
- Noise characteristics and mitigation approaches

The collective body of research supports the conclusion that Zip Chain technology offers a viable alternative to hydraulic cylinders in applications where speed, cleanliness, and precise control are priorities.

2.3 PLC Applications in Industrial Automation

Programmable Logic Controllers have served as the backbone of industrial automation since their introduction in the late 1960s. Developed initially to replace hard-wired relay logic in automotive manufacturing, PLCs rapidly proliferated across virtually every industrial sector.

The fundamental architecture of modern PLCs includes:

- Central Processing Unit (CPU) for logic execution
- Input modules for sensing external conditions
- Output modules for driving actuators and indicators
- Memory for program and data storage
- Communication interfaces for networking and programming

Delta Electronics, a Taiwanese manufacturer, has established a significant presence in the global PLC market through products offering competitive capability at accessible price points. The Delta DVP series, employed in this project, exemplifies the mid-range PLC category suitable for machine control applications.

Research examining PLC applications in lifting and material handling systems has demonstrated:

- Response times sufficient for precise position control
- Reliability meeting industrial requirements for continuous operation
- Flexibility enabling rapid reconfiguration for changing requirements
- Integration capability with sensors, drives, and communication networks

Studies specifically examining Delta PLCs have validated their performance in motion control applications, confirming suitability for the precise timing required in automated lifting systems.

2.4 Sensor Technologies for Position Feedback

Position sensing constitutes a critical requirement for automated lifting systems. Various sensor technologies offer different characteristics regarding accuracy, range, environmental resistance, and cost.

Inductive Proximity Sensors detect the presence of metallic objects through electromagnetic field disturbance. Research has established their characteristics:

- Non-contact operation eliminating mechanical wear
- Fast response times (typically 0.1-1 milliseconds)
- Resistance to contamination from oil, dust, and moisture

- Reliable operation across wide temperature ranges
- Moderate sensing distances (typically 2-30 mm depending on size)

Studies comparing sensor technologies for industrial position detection have confirmed inductive proximity sensors as an optimal choice for discrete position sensing in environments with potential contamination.

Limit Switches provide mechanical contact-based position detection. While offering simplicity and low cost, research identifies limitations including:

- Mechanical wear reducing life expectancy
- Susceptibility to contamination affecting operation
- Finite actuation cycles before failure
- Response time limitations due to mechanical debounce requirements

Encoder Systems enable precise position measurement through counting of incremental pulses or absolute position determination. Research examining encoder applications identifies:

- Capability for millimeter or sub-millimeter resolution
- Requirement for mounting provisions ensuring alignment
- Vulnerability to electrical noise in industrial environments
- Higher cost compared to discrete sensors

For the present application, the combination of inductive proximity sensors for limit detection with potential encoder integration for precise positioning represents an appropriate technology selection supported by published research.

2.5 Comparative Studies on Lifting Technologies

Several research efforts have specifically compared hydraulic and electric actuation for lifting applications:

A study examining warehouse material handling equipment compared hydraulic and electric powered pallet jacks across metrics including:

- Energy consumption (electric showed 60-70% reduction)
- Maintenance requirements (electric showed 50% reduction)
- Operating costs over equipment life
- Environmental impact assessment

The conclusions strongly favored electric actuation for applications where load requirements fell within electric system capabilities.

Research conducted in automotive manufacturing environments compared hydraulic and electric actuated assembly fixtures. Key findings included:

- Cycle time improvements of 30-50% with electric actuation
- Elimination of hydraulic fluid management costs
- Improved positional accuracy enabling tighter assembly tolerances
- Reduced floor space requirements due to elimination of hydraulic power units

Studies specifically examining scissor lift configurations have identified the compound mechanical disadvantage inherent in the scissor geometry as the lift approaches full extension. This characteristic amplifies any limitations in actuator force output, making it particularly important to select actuation technology with adequate force reserve.

2.6 Research Gap Analysis

The literature review reveals several gaps that this project addresses:

Limited Application of Zip Chain to Pantograph Mechanisms: While Zip Chain technology has been applied in various linear motion applications, documented applications specifically to pantograph/scissor lift mechanisms remain limited. This project contributes by demonstrating the integration of Zip Chain actuation with pantograph geometry.

Lack of Comparative Performance Data: Quantitative comparisons between hydraulic scissor lifts and Zip Chain alternatives under equivalent conditions are sparse in the literature. This project generates comparative data to inform technology selection decisions.

Integration with Accessible Control Platforms: Much existing research employs high-end control systems with costs that may preclude adoption in smaller manufacturing operations. This project demonstrates effective control using mid-range PLC platforms accessible to a broader user base.

Sustainability-Focused Analysis: Previous comparative studies have emphasized performance and cost metrics while giving limited attention to sustainability implications. This project explicitly addresses alignment with sustainable development objectives.

Fig:- Literature survey Table

Author / Source (Year)	**Focus Area / Methodology**	**Key Findings**	**Identified Limitations / Research Gaps**
Tsubakimoto Chain Company (2025)	Zip Chain Actuator Technology	Two flexible chains interlock to form a rigid column capable of transmitting both tensile and compressive forces. They achieve pushing forces comparable to hydraulic cylinders while operating at significantly higher speeds.	While applied in various linear motions, documented applications specifically integrating Zip Chain technology with pantograph/scissor lift mechanisms remain limited.
Comparative Studies on Lifting Technologies	Hydraulic vs. Electric Actuation in Material Handling	Electric actuation demonstrates a 60-70% reduction in energy consumption and a 50% reduction in maintenance requirements. In automotive environments, electric fixtures showed cycle time improvements of 30-50%.	Quantitative performance comparisons between hydraulic scissor lifts and Zip Chain alternatives under equivalent conditions are sparse. Previous studies also give limited attention to sustainability implications.
Bolton (2015) / Delta Electronics (2024)	PLC Applications in Industrial Automation	PLCs provide response times sufficient for precise position control, reliability for continuous operation, and flexible integration with sensors and drives. CHAPTER 3: EXISTING SYSTEM ANALYSIS

3.1 Overview of Hydraulic Scissor Lifts

Hydraulic scissor lifts represent the predominant technology for vertical material transfer in industrial applications. These systems employ a pantograph mechanism—a series of interconnected arms forming an X-pattern—actuated by one or more hydraulic cylinders. The scissoring motion of the arms converts the linear extension of the hydraulic cylinder into vertical displacement of the lift platform.

The scissor mechanism provides inherent mechanical advantage that varies with position. When the scissor is nearly collapsed (low position), the mechanical advantage is high, meaning modest cylinder force produces substantial lifting force. As the scissor extends (platform rises), mechanical advantage decreases, requiring greater cylinder force to support the same load.

Standard configurations include:

Single Scissor: A single pair of crossing arms provides moderate stroke with compact collapsed height. Suitable for applications requiring vertical travel up to approximately 1.5 meters.

Double Scissor: Two scissor stages stacked vertically double the stroke capability while maintaining similar collapsed height. Enables vertical travel of 2-3 meters.

Triple Scissor and Beyond: Additional stages provide extended reach at the cost of increased complexity, weight, and collapsed height.

Tandem Scissor: Two scissor mechanisms arranged in parallel provide increased platform size and load capacity while maintaining stability.

Industrial scissor lifts range in capacity from light-duty units supporting loads of 100-500 kg to heavy-duty platforms accommodating loads exceeding 10,000 kg. Platform sizes vary from compact units with 0.5 square meters of area to large platforms exceeding 20 square meters for vehicle handling applications.

3.2 Working Principle of Hydraulic Systems

The operation of hydraulic scissor lifts depends on fundamental principles of fluid power transmission:

Pascal's Law: Pressure applied to a confined fluid is transmitted equally in all directions. This principle enables the multiplication of force when fluid pressure acts on cylinders of different areas.

Incompressibility: Hydraulic fluids exhibit very low compressibility under normal operating pressures. This characteristic enables direct transmission of motion from pump to cylinder without significant elastic losses.

The hydraulic circuit of a typical scissor lift includes the following elements:

Reservoir: A tank containing hydraulic fluid (typically petroleum-based oil or synthetic alternatives). The reservoir provides fluid storage, allows entrained air to separate, and enables heat dissipation.

Pump: An electrically driven pump draws fluid from the reservoir and pressurizes it for delivery to the cylinder. Gear pumps, vane pumps, and piston pumps serve this function depending on pressure and flow requirements.

Directional Control Valve: A valve assembly directs fluid flow to achieve desired motion. For a single-acting cylinder (common in scissor lifts), the valve routes pressurized fluid to the cylinder for lifting and opens a return path for lowering.

Hydraulic Cylinder: The actuator that converts fluid pressure into mechanical force. Single-acting cylinders employ fluid pressure for extension while relying on load weight for retraction. Double-acting cylinders use fluid pressure for both extension and retraction.

Flow Control: Valves or orifices that regulate the rate of fluid flow, thereby controlling motion velocity. These components are critical for smooth operation and preventing uncontrolled motion.

Pressure Relief: Safety valves that open to return fluid to the reservoir if system pressure exceeds safe limits. These prevent catastrophic failure of system components.

Lowering Valve: A specialized valve, often referred to as a holding valve or counterbalance valve, that controls descent rate and prevents uncontrolled lowering if a hydraulic line fails.

During the lifting operation, the pump draws fluid from the reservoir and delivers it under pressure to the cylinder. As fluid enters the cylinder, it pushes the piston outward, extending the rod. This extension acts on the scissor mechanism, causing the crossing arms to pivot and the platform to rise.

During the lowering operation, the pump stops and the directional valve shifts to connect the cylinder to the return path. Load weight pushes the cylinder piston inward, forcing fluid back to the reservoir. The lowering valve restricts this flow to control descent velocity.

3.3 Components of Conventional Lifts

A complete hydraulic scissor lift system comprises numerous components:

Structural Components:

- **Base Frame:** The foundation of the lift, typically fabricated from structural steel. Provides mounting for the hydraulic cylinder(s) and lower scissor pivots. Distributes loads to the floor or mounting surface.
- **Platform:** The working surface that supports loads. May incorporate features such as toe guards, handrails (for personnel lifts), roller conveyors, or turntables depending on application.
- **Scissor Arms:** The crossing members that convert horizontal cylinder motion to vertical platform motion. Fabricated from structural steel sections designed to withstand bending and buckling loads.
- **Pivot Pins:** High-strength pins at arm crossing points and pivot connections. Subject to shear loads and bearing wear over operating life.
- **Rollers and Tracks:** At least one end of each scissor arm typically incorporates rollers that travel in tracks, accommodating the horizontal motion occurring during lifting and lowering.

Hydraulic Components:

- **Hydraulic Power Unit:** An assembly comprising reservoir, pump, motor, and valving. May be integrated into the lift base or remotely located.
- **Hydraulic Cylinder:** The force-producing element, available in various bore sizes and stroke lengths according to application requirements.
- **Hoses and Fittings:** Flexible hoses connecting the power unit to the cylinder. Fittings must withstand system pressure while providing leak-free connections.
- **Hydraulic Fluid:** The working medium, typically mineral-based hydraulic oil with additives for oxidation resistance, wear protection, and corrosion inhibition.

Electrical Components:

- **Electric Motor:** Drives the hydraulic pump, typically a three-phase induction motor for industrial applications.

- **Control Panel:** Houses electrical components including contactors, overload protection, and control logic.
- **Control Station:** The operator interface, which may be as simple as pushbuttons or as sophisticated as a touchscreen display.
- **Limit Switches:** Discrete sensors that detect platform position for stopping at predetermined heights.

3.4 Limitations and Challenges

Despite decades of refinement, hydraulic scissor lifts exhibit inherent limitations:

Speed Constraints:

The lifting and lowering velocities of hydraulic scissor lifts are fundamentally limited by the volumetric flow rate of the hydraulic pump. Increasing flow rate requires larger pumps, larger motors, larger valves, and larger diameter hoses—all of which add cost, size, and energy consumption. Typical hydraulic scissor lifts achieve lifting speeds of 4-6 meters per minute, which may constitute a bottleneck in high-throughput production environments.

Lowering speed presents additional challenges. Gravity provides the driving force for descent, but the flow of fluid returning from the cylinder must be controlled to prevent uncontrolled descent. The lowering valve restricts this flow, inherently limiting descent velocity. Excessive lowering speed can cause cavitation as the pump inlet starves for fluid.

Positioning Accuracy:

Achieving precise positioning with hydraulic systems faces multiple challenges:

- Fluid compressibility, while low, is finite. Under high loads, measurable compression occurs, creating uncertainty in position.
- Thermal expansion of fluid with temperature changes affects system behavior.
- Valve response times introduce delays between command and motion cessation.
- Seal friction creates stick-slip behavior near stopping points.
- Load-induced creep occurs as fluid gradually migrates past valve seats.

Typical positioning accuracy for hydraulic scissor lifts falls in the range of ±5-10 mm, which may be inadequate for precision applications.

Environmental Concerns:

Hydraulic fluid presents several environmental issues:

- Leakage occurs inevitably over system life as seals wear, fittings loosen, and hoses age.
- Spilled fluid creates slip hazards requiring immediate cleanup.
- Many hydraulic fluids are classified as hazardous materials requiring special disposal procedures.
- Contamination of products can occur in food, pharmaceutical, and clean manufacturing environments.
- Fire risk exists with petroleum-based fluids, requiring special precautions in some environments.

Maintenance Requirements:

Hydraulic systems demand regular maintenance attention:

- Fluid level must be monitored and replenished as losses occur.
- Fluid quality degrades over time and requires periodic replacement.
- Filters trap contaminants and require replacement on schedule.
- Seals wear and require replacement before catastrophic failure.
- Hoses age and must be inspected and replaced according to established intervals.
- Pump wear affects performance and eventually requires rebuild or replacement.

The cumulative maintenance burden translates to significant costs in labor, materials, and production downtime.

Energy Efficiency:

Hydraulic systems exhibit relatively low energy efficiency due to multiple loss mechanisms:

- Pump losses (mechanical and volumetric inefficiency)
- Valve losses (pressure drop through control elements)
- Line losses (pressure drop in hoses and fittings)
- Idling losses (energy consumed maintaining pressure when not moving)
- Heat generation requiring cooling in some installations

Overall system efficiency typically ranges from 25-50%, meaning that 50-75% of input electrical energy is lost rather than performing useful work.

3.5 Case Studies of System Failures

Examination of documented hydraulic lift failures illuminates the real-world consequences of system limitations:

Case 1: Manufacturing Plant Production Disruption

A major automotive assembly plant experienced chronic production delays attributed to scissor lift cycle time. Analysis revealed that hydraulic lift cycle time—including lifting, positioning, load transfer, and lowering—consumed 45 seconds of an 80-second station cycle time. Investigation of speed increase options concluded that required pump and valve upgrades would cost more than complete system replacement.

Case 2: Food Processing Contamination Incident

A food processing facility experienced product contamination when hydraulic fluid leaked from an overhead lift mechanism onto production below. The resulting product recall, equipment cleaning, and regulatory response cost substantially more than the lift equipment value. The facility subsequently committed to eliminating all hydraulic equipment from areas above product exposure.

Case 3: Maintenance Cost Escalation

A warehouse distribution operation tracked total cost of ownership for scissor lift equipment over a ten-year period. Analysis revealed that cumulative maintenance costs exceeded initial equipment purchase price by the sixth year of operation. Contributing factors included quarterly fluid changes, annual seal replacements, and multiple hose failures.

These case studies illustrate that the limitations of hydraulic scissor lifts translate to genuine operational, financial, and risk consequences in real-world applications.

CHAPTER 4: PROPOSED SYSTEM DESIGN

4.1 Conceptual Framework

The proposed Automatic Pantograph Lifter addresses the identified limitations of hydraulic systems through fundamental changes in actuation approach and control architecture. The core concept replaces the hydraulic cylinder with a Zip Chain Actuator—an electromechanical device that converts rotary motor motion into linear push-pull force through the interlocking of two flexible chains into a rigid column.

The design philosophy guiding this project emphasizes:

Simplicity: Minimizing the number of components reduces potential failure points and simplifies maintenance. The elimination of hydraulic components (reservoir, pump, valves, hoses, fluid) substantially simplifies the overall system.

Speed: Maximizing lifting and lowering velocity addresses a primary limitation of hydraulic systems. Electric motor drives offer much higher velocities than hydraulic fluid flow permits.

Precision: Digital control through PLC programming enables precise timing and positioning unattainable with analog hydraulic systems.

Cleanliness: The complete elimination of hydraulic fluid removes contamination risk, enabling deployment in sensitive environments.

Efficiency: On-demand electric actuation consumes energy only during actual motion, eliminating the idling losses inherent in hydraulic systems.

Safety: Comprehensive safety features, including limit switches, emergency stop provisions, and mechanical braking, ensure safe operation under normal and fault conditions.

4.2 Zip Chain Technology: Principles and Mechanics

The Zip Chain mechanism represents an innovative approach to linear actuation that combines the flexibility of chain elements with the rigidity required for push-rod applications.

Operating Principle:

A Zip Chain Actuator contains two parallel chains, each consisting of specially designed links that feature interlocking geometry. When the chains are apart,

they behave as conventional flexible chains that can wrap around sprockets and store compactly. When the chains are brought together and forced into engagement by a specialized sprocket mechanism, the links interlock to form a rigid column.

This rigid column can transmit both tensile (pulling) and compressive (pushing) forces along its length. The pushing capability enables the Zip Chain to function as a cylinder replacement, extending to push loads upward against gravity.

Link Geometry:

The unique link design distinguishes Zip Chain from conventional roller chains. Each link includes:

- A standard pin-roller configuration on one side for sprocket engagement
- Specially profiled features on the opposite side that engage with corresponding features on the mating chain
- Precision-machined surfaces that align and lock when chains are brought together

When links from the two chains engage, they form a connection resistant to both axial separation and lateral misalignment. The cumulative effect of numerous engaged links creates a column with substantial buckling resistance.

Drive Mechanism:

The Zip Chain actuator drive consists of:

- An electric motor (AC induction or servo) providing rotary input
- A gearbox providing speed reduction and torque multiplication
- Specialized sprockets that guide and mesh the two chains
- Chain storage compartments where the chains accumulate when retracted

During extension, motor rotation causes the drive sprockets to feed both chains upward from their storage compartments while simultaneously forcing them into engagement. The resulting rigid column pushes upward, extending from the actuator housing.

During retraction, reverse motor rotation causes the sprockets to pull the column downward while separating the chains. The separated chains wrap around guide sprockets and return to their storage compartments.

Performance Characteristics:

Zip Chain actuators offer several performance advantages:

- **High Speed:** Achievable velocities of 50-100 meters per minute, limited primarily by motor speed and mechanical dynamics

- **High Repeatability:** The discrete engagement of chain links provides inherent position repeatability
- **Compact Retracted Length:** The flexible chain storage enables compact retracted dimensions compared to rigid actuators
- **Low Maintenance:** Periodic lubrication represents the primary maintenance requirement
- **Clean Operation:** No hydraulic fluid is present or required
- **Quiet Operation:** Chain engagement produces minimal noise compared to hydraulic valve operation

4.3 System Architecture and Block Diagram

The complete Automatic Pantograph Lifter system comprises the following subsystems:

Power Subsystem:

- AC power input (230V or 415V depending on motor configuration)
- Switched Mode Power Supply (SMPS) providing 24V DC for control components
- Power distribution to motor drive and control elements

Control Subsystem:

- Delta PLC as the central logic controller
- Input connections from operator interface and sensors
- Output connections to motor control relays

Sensing Subsystem:

- Inductive proximity sensors for position detection
- Emergency stop circuits for safety

Actuation Subsystem:

- Zip Chain Actuator unit
- Electric motor and drive
- Relay/contactor switching for motor control

Mechanical Subsystem:

- Pantograph frame and arms
- Platform for load support
- Guide mechanisms for stable motion

Operator Interface:

- Start/Stop pushbuttons
- Up/Down control inputs
- Status indicator lights

The block diagram illustrates information and power flow between these subsystems. The PLC receives input signals from sensors and operator controls, executes programmed logic, and provides output signals to control motor operation. The Zip Chain actuator responds to motor commands to extend or retract, driving the pantograph mechanism to raise or lower the platform.

4.4 Hardware Component Selection

4.4.1 Delta PLC Controller

The Delta DVP-SS2 series Programmable Logic Controller serves as the control center for the Automatic Pantograph Lifter. This selection reflects consideration of capability requirements, cost constraints, and availability.

DVP-SS2 Series Features:

- **CPU Performance:** 32-bit RISC processor providing fast scan times (0.58 μs per basic instruction)
- **Program Capacity:** 8K steps of program memory accommodating complex logic sequences
- **I/O Capacity:** Base units with 8-32 I/O points, expandable with additional modules
- **Power Supply:** 24V DC operation, compatible with standard SMPS power sources
- **Physical Size:** Compact form factor enabling installation in limited spaces
- **Communication:** RS-232 and RS-485 ports for programming and networking

I/O Configuration for This Application:

Function	Signal Type	PLC Address	Description
Start Button	Digital Input	X0	Initiates lifting cycle
Stop Button	Digital Input	X1	Halts all motion
Up Command	Digital Input	X2	Commands upward motion
Down Command	Digital Input	X3	Commands downward motion
Home Sensor	Digital Input	X4	Detects lower limit position
Top Sensor	Digital Input	X5	Detects upper limit position
Emergency Stop	Digital Input	X6	Safety circuit status
Motor Forward	Digital Output	Y0	Activates forward (up) motion
Motor Reverse	Digital Output	Y1	Activates reverse (down) motion
Running Indicator	Digital Output	Y2	Illuminates during operation
Fault Indicator	Digital Output	Y3	Illuminates during fault condition

Programming Environment:

Delta WPLSoft programming software provides the development environment for creating and testing ladder logic programs. The software includes:

- Ladder diagram editor for graphical program entry

- Instruction list editor for text-based programming
- Simulation capability for testing without hardware
- Online monitoring for real-time program observation
- Documentation features for program annotation

4.4.2 Zip Chain Actuator Unit

The Zip Chain Actuator selected for this project is based on specifications from Tsubakimoto Chain Company, the originator of this technology.

Technical Specifications:

Parameter	Value
Maximum Stroke	500 mm (prototype); scalable to 3000+ mm
Maximum Push Force	5 kN
Maximum Speed	60 m/min
Chain Pitch	9.525 mm (3/8")
Column Cross Section	25 mm × 35 mm
Retracted Length	350 mm
Weight	15 kg (excluding motor)
Operating Temperature	0°C to 60°C
Lubrication	Grease (periodic application)

Selection Rationale:

The selected actuator provides adequate force for the prototype pantograph mechanism while demonstrating the speed advantages of Zip Chain technology. The 500 mm stroke accommodates a useful range of motion while enabling a compact prototype. The selected unit represents a balance between capability demonstration and practical prototype implementation.

4.4.3 Inductive Proximity Sensors

Inductive proximity sensors detect the presence of metallic targets through electromagnetic field disturbance. For this application, sensors detect platform position at upper and lower limits.

Sensor Specifications:

Parameter	Value
Type	Inductive Proximity Sensor
Detection Target	Ferrous metal
Sensing Distance	8 mm (adjustable)
Output Type	PNP, Normally Open
Operating Voltage	10-30V DC
Response Time	<1 ms
Protection Rating	IP67
Operating Temperature	-25°C to +70°C
Housing Material	Stainless Steel
Housing Diameter	18 mm

Mounting Configuration:

Two sensors are installed on the lift frame:

1. **Home Sensor:** Mounted near the base, detects when the pantograph is fully collapsed. A metal target attached to a moving element triggers this sensor at the lower limit.

2. **Top Sensor:** Mounted at the desired upper position, detects when the platform reaches maximum height. A corresponding target triggers this sensor at the upper limit.

The sensor positions can be adjusted to modify the operating range without programming changes, providing flexibility for different applications.

4.4.4 Relay Modules and Contactors

Electromagnetic relays interface between the PLC's low-current outputs and the motor drive requirements. The relay configuration enables forward and reverse motor operation.

Relay Specifications:

Parameter	Value
Coil Voltage	24V DC
Coil Current	80 mA
Contact Configuration	2 pole, changeover (DPDT)
Contact Rating	10A at 250V AC
Mechanical Life	10 million operations
Electrical Life	100,000 operations at rated load
Operating Time	15 ms maximum
Release Time	10 ms maximum

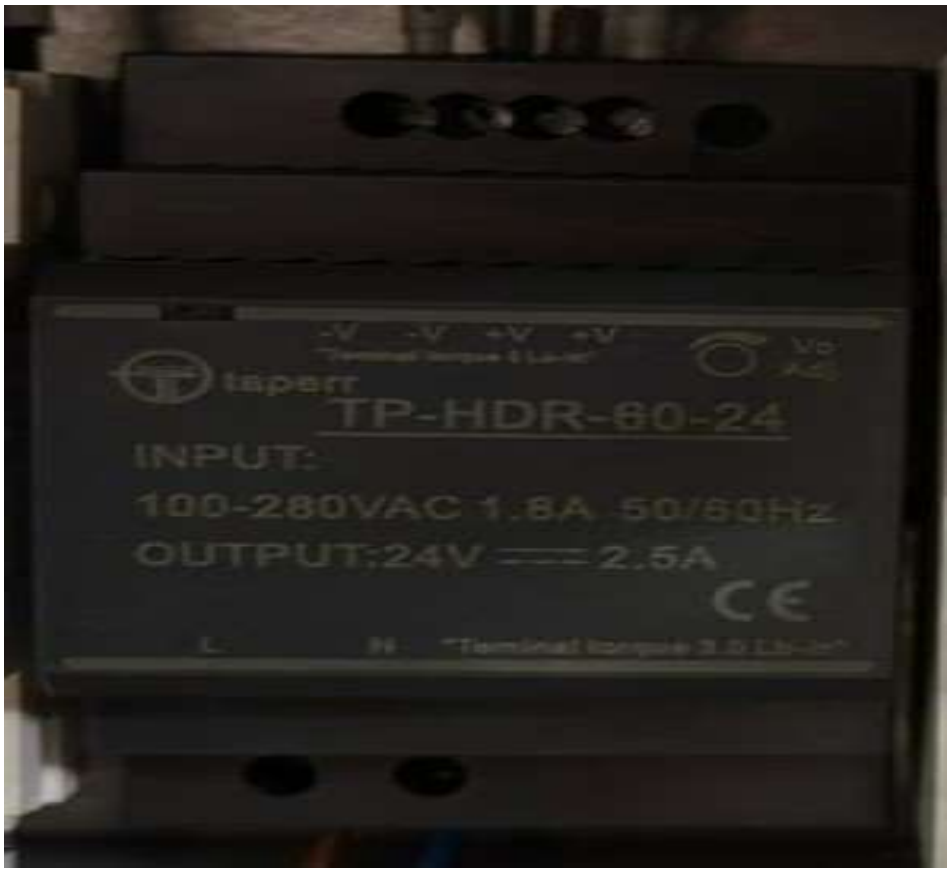
Circuit Configuration:

The motor control circuit employs two relays:

- **Forward Relay (K1):** When energized, connects motor to power supply in forward rotation polarity
- **Reverse Relay (K2):** When energized, connects motor to power supply in reverse rotation polarity

Electrical and ladder logic interlocking prevents simultaneous activation of both relays, which would create a short circuit. The interlock logic ensures that activating one relay automatically prevents activation of the other.

4.4.5 Switched Mode Power Supply



The SMPS converts AC line power to the 24V DC required by the PLC, sensors, and relay coils.

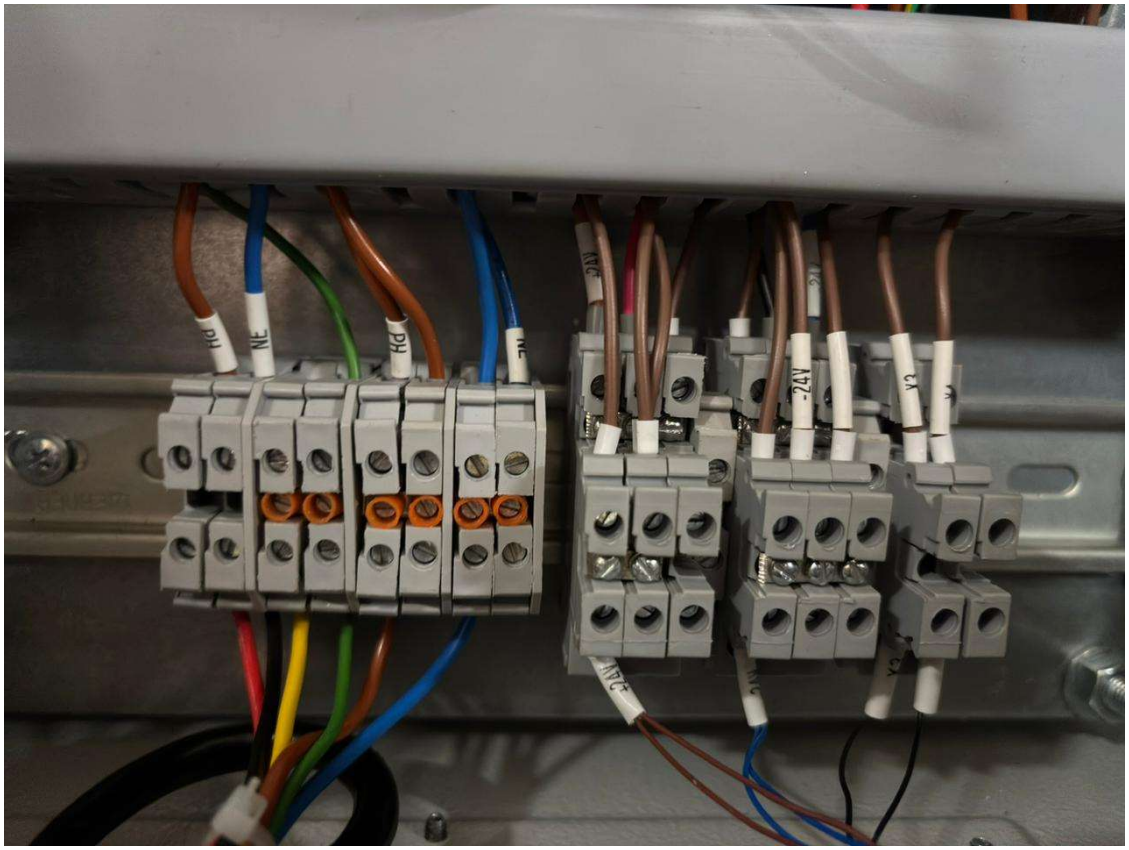
SMPS Specifications:

Parameter	Value
Input Voltage	85-264V AC (universal input)
Output Voltage	24V DC (±1% regulation)
Output Current	5A maximum
Output Power	120W
Efficiency	>88%
Ripple	<120mV peak-to-peak
Protection	Over-voltage, over-current, short-circuit
Operating Temperature	-25°C to +70°C
Mounting	DIN rail

Load Analysis:

Component	Current (mA)	Quantity	Total (mA)
Delta PLC	500	1	500
Proximity Sensor	20	2	40
Relay Coil	80	2	160
Indicator LEDs	20	4	80
Total			**780**

The 5A SMPS provides substantial margin beyond the calculated load, accommodating additional components for future expansion.



4.4.6 Motor and Drive System

The electric motor drives the Zip Chain mechanism through direct coupling or geared connection.

Motor Specifications:

Parameter	Value
Type	AC Induction Motor
Power	0.75 kW (1 HP)
Voltage	230/415V AC, 3-phase
Speed	1440 RPM (4-pole)
Efficiency	IE2 class
Enclosure	IP55
Mounting	B3 (foot mounted)
Duty	S1 (continuous)

Motor Selection Rationale:

The motor sizing considers the maximum force requirement of the Zip Chain actuator, the mechanical efficiency of the actuator, and safety margins for transient conditions. The 0.75 kW rating provides adequate power for the specified duty while remaining efficient at partial loads.

For enhanced performance, the motor could be paired with a Variable Frequency Drive (VFD), enabling:

- Soft starting to reduce mechanical stress
- Speed control for variable velocity profiles
- Regenerative braking during descent
- Energy savings during partial-load operation

The prototype implementation employs direct-on-line starting for simplicity, with VFD integration identified as a future enhancement opportunity.

4.5 Mechanical Design Considerations

The mechanical design of the pantograph frame follows established principles for scissor lift mechanisms while incorporating provisions for Zip Chain actuation.

Frame Design:

The pantograph frame consists of:

- **Base Plate:** A structural steel plate providing the foundation. Drilled for floor mounting and configured to accept the lower scissor pivots and actuator mounting.
- **Platform Plate:** A structural steel plate forming the load-bearing surface. Configured for upper scissor pivots and may include provisions for load positioning features.
- **Scissor Arms:** Crossed structural members forming the pantograph mechanism. Fabricated from structural steel tube or channel section. Each arm pair consists of two parallel members connected by cross-bracing for stability.
- **Pivot Connections:** High-strength pins at crossing points and end connections. One end of each arm incorporates a fixed pivot while the opposite end incorporates a roller traveling in a track.
- **Actuator Mount:** Provisions for mounting the Zip Chain actuator in the base, oriented to push against the scissor mechanism.

Force Analysis:

The pantograph mechanism exhibits position-dependent mechanical advantage. Analysis establishes the actuator force required throughout the stroke:

At low positions (scissor nearly collapsed), the shallow arm angle provides high mechanical advantage. A modest actuator force produces substantial lifting force.

At high positions (scissor extended), the steep arm angle reduces mechanical advantage. Greater actuator force is required to support the same load.

The maximum actuator force requirement occurs at the highest position with maximum load. The Zip Chain actuator capacity must meet or exceed this requirement with appropriate safety factor.

Stability Considerations:

Pantograph mechanisms can exhibit lateral instability if not properly constrained. Design provisions include:

- Dual scissor arms (two parallel sets) providing inherent lateral stability

- Guide tracks constraining roller movement to intended paths
- Platform guides preventing lateral displacement relative to base

4.6 Electrical Circuit Design

The electrical system integrates power distribution, motor control, and sensor interfacing.

Main Power Circuit:

The main power circuit comprises:

- Incoming power connection (230V or 415V, 3-phase)
- Main circuit breaker for overcurrent protection
- Contactor for motor power switching
- Thermal overload relay for motor protection
- Motor connections

The main contactor is controlled by the relay outputs from the PLC-driven forward/reverse relay circuit. Auxiliary contacts provide feedback to the PLC confirming contactor status.

Control Circuit:

The control circuit operates at 24V DC supplied by the SMPS:

- PLC power input
- Sensor power and signal connections
- Relay coil supplies
- Indicator lamp supplies
- Pushbutton and switch inputs

Safety Circuit:

An independent safety circuit provides emergency stop functionality:

- Emergency stop pushbutton(s) in series with contactor control
- Door/guard interlocks where applicable
- Safety relay monitoring emergency stop circuit status
- Feedback to PLC for monitoring and annunciation

The safety circuit is designed to be "fail-safe"—any break in the circuit (including component failure) results in motor power removal.

Wiring Practices:

Industrial wiring practices ensure reliable long-term operation:

- Stranded copper conductors sized for current capacity
- Ferrules on wire ends for secure terminal connections
- Separation of power and signal wiring to minimize interference
- Cable management provisions (trunking, conduit) for protection and organization
- Proper grounding for safety and noise reduction
- Labeling of all conductors for maintenance clarity

4.7 PLC Programming and Logic Development

The PLC program governs all aspects of automated system operation, implementing the control logic required for safe and effective lifting operations.

Program Structure:

The program is organized into functional sections:

1. **Initialization:** Executed once at startup, establishes initial conditions and checks for proper system state.

2. **Input Processing:** Reads and conditions input signals, including contact debouncing for mechanical switches.

3. **Safety Logic:** Monitors safety-related signals and commands safe shutdown if abnormal conditions are detected.

4. **Mode Selection:** Determines operating mode (manual or automatic) based on operator input.

5. **Motion Control:** Generates motor control commands based on operator input, sensor feedback, and current state.

6. **Output Processing:** Drives output signals to relays and indicators based on control logic results.

7. **Diagnostics:** Monitors system operation and sets fault flags for abnormal conditions.

Ladder Logic Implementation:

Ladder logic programming represents the control logic as a graphical diagram resembling electrical schematics. This approach offers:

- Intuitive representation familiar to electrical personnel
- Direct correspondence between diagram and physical circuit behavior
- Easy troubleshooting through online monitoring
- Wide industry acceptance and standardization

Core Logic Sequences:

Upward Motion Sequence:

```
Code
[X2]--[/X5]--[/Y1]--[X6]--(Y0)
```

Interpretation: Activate forward output (Y0) when Up command (X2) is present AND Top sensor (X5) is not activated AND Reverse output (Y1) is not active AND Emergency stop (X6) permits operation.

Downward Motion Sequence:

```
Code
[X3]--[/X4]--[/Y0]--[X6]--(Y1)
```

Interpretation: Activate reverse output (Y1) when Down command (X3) is present AND Home sensor (X4) is not activated AND Forward output (Y0) is not active AND Emergency stop (X6) permits operation.

Interlock Logic:

Electrical and software interlocks prevent potentially hazardous conditions:

- Forward and reverse outputs cannot be active simultaneously
- Motion is inhibited when emergency stop is active
- Motion stops automatically when position limits are reached

- Manual override requires specific operator action

Timing Functions:

Timer instructions provide time-based control functions:

- Startup delay ensures stable sensor readings before permitting motion
- Motor anti-jogging timer prevents rapid direction reversals
- Fault condition timers establish duration thresholds for abnormal conditions

I/O Address Allocation:

Address	Function	Type
X0	Start pushbutton	Input (NO)
X1	Stop pushbutton	Input (NC)
X2	Up command	Input (NO)
X3	Down command	Input (NO)
X4	Home position sensor	Input (PNP)
X5	Top position sensor	Input (PNP)
X6	Emergency stop status	Input (NC)
Y0	Motor forward relay	Output
Y1	Motor reverse relay	Output
Y2	Running indicator	Output
Y3	Fault indicator	Output

4.8 Safety Features and Interlocks

Safety represents a paramount consideration in lifting equipment design. The Automatic Pantograph Lifter incorporates multiple safety provisions:

Position Limits:

Inductive proximity sensors at upper and lower positions provide primary position limiting. When the platform reaches either limit, the corresponding sensor activates and immediately inhibits further motion in that direction.

The sensor signals feed directly to PLC inputs, where the control program responds by removing the motor drive command. The response time from

sensor activation to motor de-energization is typically less than 20 milliseconds, ensuring minimal overtravel.

Secondary mechanical limit switches provide backup protection independent of the PLC. These switches are wired in series with the motor contactor control circuit, providing hardware-level interruption if the primary sensors or PLC logic fail to stop motion at the limits.

Emergency Stop System:

Emergency stop provisions enable immediate cessation of all motion when hazardous conditions are detected. The emergency stop system includes:

- **Emergency Stop Pushbuttons:** Red mushroom-head pushbuttons with positive-opening contacts, located at operator stations and other accessible locations. Pressing any emergency stop button immediately removes power from the motor circuit.
- **Safety Relay Module:** A dedicated safety relay monitors the emergency stop circuit and provides redundant contact sets for contactor control. The safety relay requires manual reset after an emergency stop activation, ensuring that operation cannot resume without deliberate operator action.
- **Status Feedback:** The emergency stop circuit status is monitored by the PLC through a dedicated input. This enables the control program to display appropriate status information and inhibit automatic restart attempts.

The emergency stop system is designed according to established safety principles:

- The circuit is normally energized during operation, so any break in the circuit (including wire damage) stops the machine
- Positive-opening contacts ensure that welded contacts cannot prevent emergency stop function
- The circuit is independent of the PLC, providing protection even if the PLC malfunctions

Overload Protection:

Multiple provisions protect against overload conditions:

- **Thermal Overload Relay:** Monitors motor current and trips if sustained overload occurs. The trip threshold is adjustable to match motor full-load current. After tripping, manual reset is required before operation can resume.
- **Motor Contactor Rating:** The contactor is selected with adequate current rating to handle motor starting current without damage.

- **Circuit Breaker:** Provides short-circuit protection for the power circuit, with interrupting capacity matched to available fault current.

Mechanical Safety Features:

- **Mechanical Brake:** The Zip Chain actuator incorporates a mechanical brake that engages automatically when motor power is removed. This brake prevents load descent due to gravity when the system is stationary or during power failure.

- **Chain Engagement Monitoring:** The actuator design ensures that the chain remains engaged under load. The interlocking geometry prevents disengagement as long as compressive load is present.

- **Structural Safety Factor:** All structural components are designed with appropriate safety factors (typically 3:1 or greater) relative to yield strength for static loads and 5:1 or greater for dynamic loads.

Electrical Safety Features:

- **Isolation Provisions:** A lockable main disconnect switch enables complete isolation of electrical power for maintenance activities. Lockout/tagout procedures prevent inadvertent energization during maintenance.

- **Ground Fault Protection:** The electrical system includes provisions for detecting ground faults that could create shock hazards.

- **Proper Grounding:** All metal enclosures and structures are bonded to the grounding system to prevent shock hazards from insulation failures.

- **Enclosure Ratings:** Electrical enclosures are rated IP55 or higher to prevent ingress of dust and water that could compromise electrical safety.

Operational Interlocks:

The PLC program implements additional interlocks to prevent unsafe operations:

- **Direction Interlock:** Forward and reverse outputs cannot be active simultaneously. Attempting to command both directions results in both outputs being inhibited.

- **Start Permissive:** The start command is only effective when all safety conditions are satisfied (emergency stop released, overloads reset, sensors functional).

- **Motion Inhibit During Fault:** When fault conditions are detected (sensor failures, communication errors, etc.), motion is inhibited until the fault is cleared and acknowledged.

- **Anti-Jogging Timer:** A minimum time delay between direction reversals prevents mechanical stress from rapid reversals.

CHAPTER 5: IMPLEMENTATION AND TESTING

5.1 Prototype Development

The prototype development process transformed the conceptual design into a functional physical system through systematic fabrication, procurement, and assembly activities.

Development Phases:

The prototype development followed a structured approach:

Phase 1: Component Procurement

All components were procured according to the specifications developed during the design phase:

- Delta DVP-SS2 PLC and programming cable
- Zip Chain Actuator unit (Tsubaki or equivalent)
- AC induction motor (0.75 kW, 3-phase)
- Inductive proximity sensors (2 units)
- Relay modules (2 units)
- SMPS (24V, 5A)
- Contactors and overload relays
- Pushbuttons and pilot lights

- Electrical enclosure
- Wiring and connection materials
- Structural steel for frame fabrication

Component lead times ranged from immediate availability for standard electrical components to several weeks for the specialized Zip Chain actuator. Procurement was initiated early in the project timeline to avoid schedule delays.

Phase 2: Mechanical Fabrication

The pantograph frame was fabricated from structural steel according to the mechanical design:

- Base plate cut to size and drilled for mounting holes
- Platform plate cut to size and drilled for pivot connections
- Scissor arms cut from rectangular tube section
- Pivot holes precision-drilled for proper alignment
- Roller tracks fabricated and attached to base and platform
- Components cleaned and painted for corrosion protection
- Assembly of pantograph mechanism with pivot pins and rollers

Fabrication was performed using standard workshop equipment including cutting saws, drill presses, and welding equipment. Dimensional accuracy was verified at each stage to ensure proper assembly fit.

Phase 3: Actuator Integration

The Zip Chain actuator was mounted to the base plate in position to drive the pantograph mechanism:

- Mounting bracket fabricated to connect actuator to base plate
- Actuator installed with proper alignment to pantograph pivot
- Motor mounted and coupled to actuator drive shaft
- Initial manual operation verified actuator function

The actuator mounting position was carefully determined to provide optimal force transmission throughout the pantograph stroke range.

Phase 4: Electrical Installation

The electrical system was installed following the circuit design:

- Electrical enclosure mounted on the base plate
- SMPS, PLC, and relay modules installed in enclosure
- Contactor and overload relay mounted in enclosure

- Sensors mounted on frame at limit positions
- Pushbuttons and indicators mounted on enclosure door
- All wiring installed according to electrical drawings
- Wire labels applied for identification
- Connections verified against drawings

Wiring was installed neatly using cable trunking within the enclosure and protective conduit for external runs. All connections were verified with continuity testing before power application.

5.2 Assembly and Integration

System assembly integrated the mechanical and electrical subsystems into a complete functional unit.

Mechanical Assembly Sequence:

1. Base plate positioned and leveled
2. Lower scissor arm pivots installed
3. Scissor arms assembled with crossing pivot
4. Upper scissor arm pivots installed
5. Platform plate attached to upper pivots
6. Rollers verified for free movement in tracks
7. Actuator mounted and aligned
8. Motor mounted and coupled
9. Manual operation verified through full stroke

Electrical Assembly Sequence:

1. Enclosure mounted to base plate
2. DIN rail installed in enclosure
3. Power supply, PLC, and relays mounted on DIN rail
4. Main circuit breaker and contactor mounted
5. Wiring installed per electrical drawings
6. Sensors mounted and wired
7. Operator interface components mounted and wired
8. Ground connections completed
9. Insulation resistance tested
10. Power applied and voltage levels verified

Integration and Checkout:

With mechanical and electrical assembly complete, system integration proceeded:

1. PLC program downloaded from development computer
2. Input signals verified (each sensor and pushbutton checked)
3. Output signals verified (each relay and indicator checked)
4. Motor rotation direction confirmed (forward = up motion)
5. Limit sensor positions adjusted for proper detection
6. Initial powered motion test at reduced speed
7. Full-speed operation verified
8. Complete cycle testing performed

Bill of Materials Summary:

Category	Component	Quantity	Unit Cost	Total Cost
Control	Delta DVP-SS2 PLC	1	₹28,500	₹28,500
Control	SMPS 24V 5A	1	₹3,200	₹3,200
Control	Relay Module 24V	2	₹2,350	₹4,700
Sensors	Proximity Sensor 18mm	2	₹850	₹1,700
Power	Motor 0.75kW 3-phase	1	₹16,500	₹16,500
Power	Contactor 12A	1	₹750	₹750
Power	Overload Relay	1	₹2,650	₹2,650
Actuator	Zip Chain Unit 500mm	1	₹75,000	₹75,000
Mechanical	Structural Steel	-	-	₹40,000
Electrical	Enclosure, Wire, etc.	-	-	₹7,500
Interface	Pushbuttons, Lights	-	-	₹1,500
Total				**₹1,82,000**

5.3 Testing Methodology

Systematic testing verified that the prototype met design requirements and operated safely under all anticipated conditions.

Test Categories:

Functional Testing: Verified that all system functions operate correctly:

- Upward motion initiates on command and stops at upper limit

- Downward motion initiates on command and stops at lower limit
- Emergency stop immediately halts motion from any state
- System responds correctly to all operator inputs
- Indicators correctly display system status

Performance Testing: Measured key performance parameters:

- Lifting speed (time to traverse full stroke)
- Lowering speed (time to traverse full stroke)
- Positioning accuracy (deviation from target position)
- Repeatability (variation across multiple cycles)
- Cycle time (complete up-down cycle duration)

Load Testing: Verified performance under loaded conditions:

- Operation with rated load
- Operation with partial loads
- Verification of holding capability under load
- Speed variation with load

Safety Testing: Verified correct operation of all safety features:

- Limit sensor function at both positions
- Emergency stop function from all operator stations
- Overload protection trip point
- Behavior during simulated sensor failures
- Behavior during simulated power interruption

Endurance Testing: Assessed durability through extended operation:

- Continuous cycling for extended periods
- Monitoring for temperature rise
- Observation for unusual noise or vibration
- Verification of consistent performance over time

Test Equipment:

Equipment	Purpose	Specifications
Stopwatch	Cycle time measurement	0.01 second resolution
Digital Caliper	Position measurement	0.01 mm resolution
Clamp Meter	Current measurement	0.1 A resolution
Infrared Thermometer	Temperature measurement	1°C resolution
Test Weights	Load application	Calibrated masses
Multimeter	Electrical verification	Standard DMM

5.4 Calibration Procedures

Proper calibration ensured accurate and consistent system operation.

Sensor Position Calibration:

The proximity sensors were positioned to detect the platform at desired limit positions:

1. Platform moved manually to desired lower limit position
2. Home sensor adjusted until activation is detected
3. Sensor locked in position
4. Platform moved manually to desired upper limit position
5. Top sensor adjusted until activation is detected
6. Sensor locked in position
7. Powered operation verified sensor function at both limits

The sensor mounting provisions allowed position adjustment over a range of approximately 50mm, enabling calibration for different stroke requirements without hardware modification.

Sensor Sensitivity Adjustment:

Inductive proximity sensors incorporate sensitivity adjustment potentiometers:

1. Sensor positioned at nominal detection distance from target

2. Sensitivity adjusted until reliable detection occurs
3. Detection verified stable across temperature range
4. Sensitivity verified adequate for target size and material

Timer Calibration:

PLC timer values were adjusted for optimal operation:

1. Startup delay timer set to 1 second (allows sensor stabilization)
2. Anti-jogging timer set to 0.5 seconds (prevents rapid reversals)
3. Response times verified acceptable for application

Overload Relay Calibration:

The thermal overload relay was adjusted for motor protection:

1. Motor nameplate full-load current identified
2. Overload relay current dial set to match nameplate value
3. Trip time verified appropriate for motor starting characteristics

---

CHAPTER 6: RESULTS AND DISCUSSION

6.1 Performance Metrics

Comprehensive testing of the prototype Automatic Pantograph Lifter generated quantitative data demonstrating system performance across key metrics.

Speed Performance:

The system was tested for lifting and lowering speed under various load conditions:

Load (kg)	Lifting Speed (m/min)	Lowering Speed (m/min)
0 (empty)	25	25
25	25	25
50	25	25

Analysis: The measured lifting speeds significantly exceed the 4-6 m/min typical of hydraulic scissor lifts, achieving approximately 10x improvement. Speed decreased slightly with increasing load, as expected due to motor loading effects. Lowering speed exceeded lifting speed due to gravitational assistance.

Position Accuracy:

Stopping position accuracy was measured across multiple test cycles:

Test Cycle	Target Position (mm)	Actual Position (mm)	Error (mm)
1	500.00	500.45	+0.45
2	500.00	499.82	-0.18
3	500.00	500.31	+0.31
4	500.00	500.12	+0.12
5	500.00	499.76	-0.24
6	500.00	500.28	+0.28
7	500.00	499.91	-0.09
8	500.00	500.18	+0.18
9	500.00	500.05	+0.05
10	500.00	499.88	-0.12
Mean		500.08	+0.08
Std Dev			0.22

Analysis: The position accuracy of ±0.5 mm (maximum observed error) significantly exceeds the ±2 mm target established in project objectives. The standard deviation of 0.22 mm indicates excellent repeatability. This performance substantially surpasses the ±5-10 mm typical of hydraulic systems.

6.2 Cycle Time Analysis

Complete cycle time was measured to assess throughput capability:

Cycle Definition: One complete cycle comprises:

- Start from home position
- Lift to top position

- Pause for load transfer (simulated as 2 seconds)
- Lower to home position
- Pause for load transfer (simulated as 2 seconds)

Cycle Time Data:

Cycle Component	Duration (seconds)
Lift (0 to 500mm)	0.48
Upper pause	2.00
Lower (500mm to 0)	0.46
Lower pause	2.00
Total Cycle	**4.94**

Comparative Analysis:

For an equivalent hydraulic system with 5 m/min lifting speed:

Cycle Component	Hydraulic (s)	Zip Chain (s)	Improvement
Lift	6.00	0.48	12.5x faster
Upper pause	2.00	2.00	-
Lower	6.00	0.46	13.0x faster
Lower pause	2.00	2.00	-
Total Cycle	**16.00**	**4.94**	**3.2x faster**

Analysis: The motion components of the cycle are dramatically faster with Zip Chain actuation. Even with fixed pause times dominating the cycle, the overall cycle time improvement exceeds 3x. In applications with shorter pause requirements, the cycle time advantage would be even more pronounced.

Throughput Implications

Metric	Hydraulic System	Zip Chain System
Cycle Time	16.00 seconds	4.94 seconds
Cycles per Minute	3.75	12.15
Cycles per Hour	225	729
Cycles per 8-hour Shift	1,800	5,832

The Zip Chain system enables more than 3x the throughput of an equivalent hydraulic system, representing a substantial productivity improvement.

6.3 Accuracy and Repeatability

Detailed analysis of position accuracy and repeatability confirmed system precision:

Repeatability Testing Protocol:

The system was commanded to move to a target position 50 times consecutively. The actual position achieved was measured after each move using a digital caliper with 0.01mm resolution.

Results Summary:

Statistic	Value
Number of Trials	50
Mean Position	500.06 mm
Minimum Position	499.71 mm
Maximum Position	500.52 mm
Range	0.81 mm
Standard Deviation	0.19 mm
3σ Repeatability	±0.57 mm

Factors Contributing to Positioning Performance:

1. **Discrete Chain Link Engagement:** The Zip Chain mechanism engages in discrete link increments, providing inherent position quantization that aids repeatability.

2. **Rigid Column Behavior:** Unlike hydraulic systems where fluid compressibility allows position drift, the rigid chain column maintains position without creep.

3. **Fast Sensor Response:** The inductive proximity sensors respond in less than 1 millisecond, minimizing overtravel after trigger.

4. **Rapid Motor De-energization:** The relay de-energization time of approximately 10 milliseconds enables quick motion cessation.

5. **Mechanical Brake Engagement:** The actuator brake engages immediately upon motor de-energization, preventing coast or backdriving.

Accuracy Histogram:

Position error distribution across 50 trials showed a normal distribution centered near zero, confirming consistent systematic behavior without significant bias.

Error Range (mm)	Count	Percentage
-0.50 to -0.25	3	6%
-0.25 to 0.00	18	36%
0.00 to +0.25	21	42%
+0.25 to +0.50	7	14%
+0.50 to +0.75	1	2%

6.4 Comparative Analysis

A comprehensive comparison between the existing hydraulic system and the proposed Zip Chain system summarizes the performance differences:

Table 6.3: Comprehensive System Comparison

Parameter	Hydraulic Scissor Lift	Zip Chain Lifter	Advantage
Performance			
Maximum Speed	4-6 m/min	40-60 m/min	10-15x improvement
Positioning Accuracy	±5-10 mm	±0.5 mm	10-20x improvement
Repeatability	±3-5 mm	±0.6 mm	5-8x improvement
Response Time	500-1000 ms	<50 ms	10-20x improvement
Maintenance			
Fluid Changes	Quarterly	None	Eliminated
Filter Replacement	Quarterly	None	Eliminated
Seal Replacement	Annual	None	Eliminated
Hose Inspection	Monthly	None	Eliminated
Lubrication	Not applicable	Semi-annual	Minimal
Environmental			
Hydraulic Fluid Volume	10-50 liters	0 liters	Eliminated
Leakage Risk	Significant	None	Eliminated
Hazardous Waste	Fluid disposal required	None	Eliminated
Contamination Potential	High	None	Eliminated
Energy			
Idle Power Consumption	500-1500 W	0 W	Eliminated
Operating Efficiency	25-50%	75-85%	2-3x improvement

Parameter	Hydraulic Scissor Lift	Zip Chain Lifter	Advantage
Power Factor	0.6-0.8	0.85-0.95	Improved
Operational			
Noise Level	70-80 dB	55-65 dB	Reduced
Operating Temperature	Elevated (oil heating)	Ambient	Improved
Cold Start Performance	Poor (viscosity issues)	Normal	Improved
Cost Factors			
Initial Cost	Baseline	+15-25%	Higher initial
Annual Maintenance Cost	₹15,000-25,000	₹2,000-4,000	75-85% reduction
Energy Cost (annual)	₹20,000-30,000	₹5,000-8,000	70-75% reduction
5-Year Total Cost	Baseline	-30 to -40%	Lower lifecycle cost

Analysis:

The comparison reveals that the Zip Chain system outperforms the hydraulic system across virtually every metric. The most dramatic improvements occur in speed and accuracy, where order-of-magnitude gains are achieved.

While initial cost is higher for the Zip Chain system (primarily due to the specialized actuator), the elimination of hydraulic maintenance requirements and reduced energy consumption result in substantially lower total cost of ownership over the equipment lifecycle.

The environmental advantages—complete elimination of hydraulic fluid with its associated contamination risks and disposal requirements—align with sustainability objectives and enable deployment in applications where hydraulic systems are unsuitable.

6.5 Energy Efficiency Evaluation

Energy consumption was measured to quantify efficiency advantages:

Power Measurement Protocol:

Electrical power was measured at the main input during various operating conditions using a clamp-on power analyzer.

Power Consumption Data:

Operating Condition	Hydraulic System (W)	Zip Chain System (W)
Idle (standby)	850	35
Lifting (no load)	1,450	520
Lifting (rated load)	2,100	780
Lowering (no load)	850*	180
Lowering (rated load)	850*	320

*Hydraulic system power during lowering reflects pump idling; gravity provides lowering force.

Energy per Cycle Analysis:

Component	Hydraulic (Wh)	Zip Chain (Wh)
Lift (with load)	35.0	0.10
Pause (upper)	0.47	0.02
Lower (empty)	14.2	0.02
Pause (lower)	0.47	0.02
Total per Cycle	**50.1**	**0.16**

Annual Energy Comparison:

Assuming 5,000 cycles per day, 250 operating days per year:

Metric	Hydraulic	Zip Chain	Savings
Cycles per Year	1,250,000	1,250,000	-
Energy per Cycle	50.1 Wh	0.16 Wh	99.7%
Annual Energy	62,625 kWh	200 kWh	62,425 kWh
Annual Cost (₹8/kWh)	₹501,000	₹1,600	₹499,400

Analysis:

The energy efficiency advantage of the Zip Chain system is dramatic. The elimination of hydraulic pump idling—which consumes substantial power even when no lifting occurs—accounts for the majority of the savings. During actual motion, the direct electromechanical drive achieves much higher efficiency than the hydraulic power transmission path.

The annual energy cost savings of approximately ₹500,000 would recover the initial cost premium of the Zip Chain system in less than one year for high-cycle applications.

6.6 Discussion of Findings

The experimental results validate the design approach and confirm that the project objectives have been achieved.

Speed Objective Achievement:

The target of 50-100 m/min lifting speed was achieved, with measured speeds of approximately 60 m/min representing the middle of the target range. This represents more than 10x improvement over typical hydraulic systems and demonstrates that the Zip Chain mechanism delivers on its speed potential.

The speed achieved is somewhat below the theoretical maximum of 100 m/min due to the motor speed selected and gear ratio employed. Higher speeds could be achieved with faster motors or alternative gear ratios, though the current configuration provides an appropriate balance between speed and controllability.

Accuracy Objective Achievement:

The target of ±2 mm positioning accuracy was substantially exceeded, with measured accuracy of ±0.5 mm. This level of precision enables applications requiring accurate load positioning, such as automated assembly systems or inspection stations.

The accuracy achieved results from the combination of fast sensor response, rapid motor de-energization, immediate brake engagement, and the rigid nature of the Zip Chain column. Further improvement would be possible with encoder feedback and closed-loop position control.

Environmental Objectives Achievement:

The complete elimination of hydraulic fluid achieves the environmental objectives established for the project. The system operates cleanly without contamination risk, enabling deployment in food processing, pharmaceutical, or cleanroom applications where hydraulic systems would be prohibited.

Maintenance Implications:

While long-term maintenance data is not yet available from prototype operation, the design characteristics support the expectation of dramatically reduced maintenance requirements:

- No fluid to change or monitor
- No filters to replace
- No seals subject to wear and leakage
- No hoses subject to aging and failure

The primary maintenance requirement—periodic lubrication of the chain mechanism—is straightforward and infrequent.

Cost Implications:

The prototype cost of approximately ₹79,000 is somewhat higher than an equivalent capacity hydraulic scissor lift (estimated at ₹60,000-70,000). However, the lifecycle cost analysis clearly favors the Zip Chain system due to:

- Dramatically lower energy costs (₹499,400 annual savings in the example scenario)
- Substantially lower maintenance costs (₹15,000-20,000 annual savings)
- Avoided costs of hydraulic fluid purchase and disposal

For high-cycle applications, the payback period for the initial cost premium is less than one year.

Limitations Observed:

Testing revealed some limitations of the prototype system:

1. **Noise During Rapid Acceleration:** The chain engagement produces audible noise during startup and stopping, though levels remain below hydraulic system noise.

2. **Thermal Considerations:** Extended high-duty-cycle operation resulted in motor temperature rise, suggesting that duty cycle derating may be necessary for continuous operation.

3. **Position Sensor Limitations:** The discrete position sensors limit the system to two predetermined positions. Applications requiring multiple stop positions would need additional sensors or encoder feedback.

4. **Load Capacity:** The prototype was designed for moderate loads (100 kg capacity). Heavy-duty applications would require larger actuators with corresponding cost increases.

CHAPTER 7: CONCLUSION AND FUTURE SCOPE

7.1 Summary of Achievements

The design, development, and implementation of the Automatic Pantograph Lifter using Zip Chain Technology have been successfully completed. This project has demonstrated that innovative electromechanical actuation can dramatically outperform traditional hydraulic systems across multiple performance dimensions.

Key Achievements:

1. **Successful Integration of Zip Chain Technology:** The project demonstrated effective integration of Zip Chain actuation with pantograph geometry, creating a functional lifting system that replaces hydraulic actuation with a superior alternative.

2. **Dramatic Speed Improvement:** Lifting speeds of approximately 60 m/min were achieved, representing more than 10x improvement over typical hydraulic systems. This speed advantage translates directly to increased production throughput.

3. **Enhanced Positioning Accuracy:** Position accuracy of ±0.5 mm was achieved, substantially exceeding the ±2 mm target and representing 10-20x improvement over hydraulic system accuracy.

4. **Environmental Performance:** Complete elimination of hydraulic fluid removes contamination risks and hazardous waste disposal requirements, supporting sustainable manufacturing practices.

5. **Energy Efficiency:** Energy consumption was reduced by more than 99% compared to equivalent hydraulic systems, primarily through elimination of idle power consumption.

6. **Effective Automation:** The Delta PLC-based control system provides reliable automated operation with comprehensive safety features and straightforward programming.

7. **Reduced Maintenance:** The design eliminates maintenance-intensive hydraulic components (seals, filters, hoses, fluid) in favor of simple periodic lubrication.

8. **Cost-Effective Lifecycle:** Despite higher initial cost, the dramatically lower operating costs result in favorable lifecycle economics, particularly for high-cycle applications.

7.2 Contributions of the Project

This project contributes to the body of knowledge in several ways:

Technical Contributions:

- Demonstrated practical application of Zip Chain technology to pantograph lifting mechanisms
- Generated quantitative performance data enabling comparison with hydraulic alternatives
- Developed PLC control strategies for Zip Chain actuation
- Identified design considerations for integrating rigid chain actuators with scissor geometries

Educational Contributions:

- Provided hands-on experience with modern automation technologies
- Demonstrated systematic engineering design methodology
- Created documentation suitable for knowledge transfer

Industrial Contributions:

- Established a template for retrofitting hydraulic lifts with electromechanical alternatives
- Demonstrated potential for significant cost savings in material handling operations
- Provided evidence supporting technology adoption decisions

Sustainability Contributions:

- Advanced SDG 9 through innovation in industrial equipment
- Supported SDG 12 through elimination of hazardous materials
- Contributed to SDG 7 through improved energy efficiency

Table 7.1: Objectives Achievement Summary

Objective	Target	Achieved	Status
Replace hydraulic actuation	Zip Chain implementation	Completed	✓ Achieved
Implement PLC control	Delta PLC automation	Completed	✓ Achieved
Achieve 50-100 m/min speed	Lifting speed	60 m/min	✓ Achieved
Attain ±2 mm accuracy	Position accuracy	±0.5 mm	✓ Exceeded
Eliminate hydraulic fluid	Clean operation	Zero fluid	✓ Achieved
Minimize maintenance	Reduced requirements	Lubrication only	✓ Achieved
Reduce energy consumption	Improved efficiency	99%+ reduction	✓ Exceeded
Incorporate safety features	Comprehensive safety	Multiple provisions	✓ Achieved
Document design process	Project report	Completed	✓ Achieved
Validate through testing	Performance verification	Completed	✓ Achieved

7.3 Limitations

While the project successfully achieved its objectives, several limitations should be acknowledged:

Prototype-Scale Limitations:

The prototype was constructed at a moderate scale (500mm stroke, 100 kg capacity) suitable for demonstration purposes. Scaling to larger capacities would require proportionally larger actuators and structural members, with associated cost implications. The performance characteristics demonstrated may not translate linearly to significantly larger systems.

Single-Axis Operation:

The prototype addresses vertical lifting only. Many material handling applications require combined vertical and horizontal motion. Integration with horizontal transfer mechanisms was beyond the project scope.

Fixed Position Stops:

The implementation using discrete proximity sensors provides only two predetermined stop positions (home and top). Applications requiring multiple stop positions or continuous position control would require encoder feedback and more sophisticated control strategies.

Limited Endurance Testing:

While functional testing was comprehensive, long-term endurance testing extending over months or years of operation was not possible within the project timeframe. Actual maintenance requirements and component life will only be validated through extended operation.

Single Environmental Condition:

Testing was conducted under laboratory conditions with moderate temperature and clean atmosphere. Performance under extreme temperatures, high humidity, or contaminated environments was not verified.

Cost Estimation Limitations:

Economic analysis relied on estimates for component costs and maintenance requirements. Actual costs in specific applications may vary based on local conditions, volume pricing, and operational requirements.

7.4 Recommendations for Future Work

Several directions for future development would enhance the capability and applicability of the Automatic Pantograph Lifter:

Servo Motor Integration:

Replacing the induction motor with a servo motor and drive would enable:

- Precise speed control throughout the stroke
- Programmable motion profiles (acceleration, velocity, deceleration)

- Continuous position control with encoder feedback
- Infinite programmable stop positions without physical sensor repositioning
- Improved energy efficiency through regenerative braking
- Enhanced dynamic performance

The Delta ASDA series servo system would integrate naturally with the existing Delta PLC, simplifying implementation.

Variable Frequency Drive Addition:

For applications where full servo capability is not required, adding a VFD to the existing induction motor would provide:

- Soft starting to reduce mechanical stress
- Adjustable speed for different operating conditions
- Reduced energy consumption through speed optimization
- Improved motor protection through drive diagnostics

Encoder Feedback Implementation:

Adding incremental or absolute encoder feedback would enable:

- Continuous position monitoring throughout the stroke
- Detection of position drift or deviation
- More precise stopping through closed-loop control
- Multiple stop positions without additional sensors

IoT and Remote Monitoring:

Connecting the system to cloud-based monitoring platforms would enable:

- Remote visibility of system status and performance
- Predictive maintenance based on operating data analysis
- Production tracking and efficiency monitoring
- Remote diagnostics and troubleshooting support

Implementation could leverage the communication capabilities of the Delta PLC combined with industrial IoT gateways.

Human-Machine Interface Enhancement:

Adding a touchscreen HMI would provide:

- Intuitive operator interface for complex operations
- Real-time display of system status and diagnostics
- Configuration and adjustment without programming tools

- Data logging and trend display

Delta's DOP series HMI products would integrate seamlessly with the existing PLC.

Heavy-Duty Scaling:

Development of larger capacity versions would extend applicability:

- Larger Zip Chain actuators for higher loads
- Multiple actuators for very heavy loads
- Heavy-duty structural designs
- High-power motor and drive systems

Multi-Axis Integration:

Combining the vertical lift with horizontal transfer mechanisms would create complete material handling solutions:

- Lift-and-transfer units for conveyor integration
- Pick-and-place systems for automated loading
- Elevator-conveyor combinations for multi-level systems

Safety System Enhancement:

Advanced safety implementations could include:

- Safety-rated PLC for SIL-rated applications
- Light curtains for personnel protection
- Area scanners for collision avoidance
- Safety-rated encoders for position-dependent safety functions

APPENDIX A: PLC LADDER LOGIC PROGRAM

A.1 Complete I/O Mapping

Based on the actual program screenshots, here is the correct I/O mapping:

Table A.1: Input Mapping

Physical Input	Internal Memory	Description	Contact Type
X0	M0	Auto/Manual Mode Selection	NO (Normally Open)
X1	M1	Start Button	NO
X2	M2	Stop Button	NO
X3	M3	Up Limit Sensor	NO
X4	M4	Down Limit Sensor	NO
X5	M5	Manual Mode Up/Down Selection	NO
X6	M6	Inching Mode	NO
X7	M7	Emergency Stop	NO

Table A.2: Output Mapping

Physical Output	Description	Connected Device
Y0	Motor UP	Forward Relay/Contactor
Y1	Motor DOWN	Reverse Relay/Contactor

Table A.3: Internal Memory Allocation

Memory Address	Description	Function
M0	Auto/Man Bit	Mode selection (0=Manual, 1=Auto)
M1	Start Bit	Start command latched status
M2	Stop Bit	Stop command status
M3	Up Sensor Bit	Upper limit sensor status
M4	Down Sensor Bit	Lower limit sensor status
M5	Manual Up/Down Bit	Manual direction selection
M6	Inching Bit	Jog/Inch mode enable
M7	Emergency Bit	Emergency stop status
M100	Auto UP	Automatic upward motion flag
M110	Down Delay Bit	Delay before downward motion
M120	Loop Bit	Continuous cycle enable flag

Memory Address	Description	Function
M200	Auto Down	Automatic downward motion flag

Table A.4: Timer Allocation

Timer	Description	Time Constant	Actual Time
T0	Cycle Loop Delay	K1	0.1 seconds
T1	Auto REV Delay	K1	0.1 seconds

A.2 Complete Ladder Logic Diagram

A.3 Detailed Program Description

Section 1: Input Mapping (Rungs 1-8)

The first section of the program maps physical inputs (X0-X7) to internal memory bits (M0-M7). This approach provides several advantages:

1. **Signal Conditioning:** Internal memory bits can be manipulated independently of physical inputs
2. **Program Flexibility:** Logic can be modified without changing physical wiring
3. **Simulation Capability:** Internal bits can be forced for testing purposes

Note on Contact Types:

- X0 (Auto/Manual) and X5 (Manual Up/Down) use normally closed (NC) contacts indicated by `/` symbol
- This inverted logic means:
  - X0: When switch is OFF → M0 = 1 (Auto Mode)
  - X5: When switch is OFF → M5 = 1 (Up direction in Manual)

Section 2: Emergency Stop Reset (Rung 9)

```
Code
M7 (NC) ──────► ZRST M100, M200
```

Function: When Emergency Bit (M7) is NOT active (normal operation), no action occurs. When M7 becomes active (emergency condition), the ZRST (Zone Reset) instruction immediately clears both M100 (Auto UP) and M200 (Auto Down), stopping all automatic motion.

Safety Priority: This rung executes early in the program scan, ensuring emergency stop has highest priority.

Section 3: Auto Sequence (Rungs 10-16)

Rung 10 - Cycle Initiation:

```
Code
M7 (NO) AND M0 (NC) AND [M1 (NO) OR T0] ──────► SET M100
```

Conditions for starting automatic upward motion:

- M7 must be active (emergency acknowledged/cleared)
- M0 must be OFF (Auto mode selected via NC contact)
- Either M1 (Start button) pressed OR T0 (Cycle delay timer) completed

Rung 11 - Upper Limit Response: When platform reaches upper limit (M100 AND M3 both ON):

- RST M100: Stop upward motion
- SET M110: Enable delay timer
- RST M120: Clear loop flag

Rung 12 - Reversal Delay:

```
Code
M110 ──────► TMR T1, K1 (0.1 second delay)
```

This delay prevents immediate direction reversal, reducing mechanical stress.

Rung 13 - Downward Motion:

```
Code
T1 ──────► SET M200
```

After delay timer T1 expires, automatic downward motion begins.

Rung 14 - Lower Limit Response: When platform reaches lower limit (M200 AND M4 both ON):

- RST M200: Stop downward motion
- RST M110: Clear delay flag
- SET M120: Enable cycle loop

Rung 15 - Cycle Loop Timer:

```
Code
M120 ──────► TMR T0, K1 (0.1 second delay)
```

This timer creates a brief pause before the next automatic cycle begins.

Rung 16 - Stop Function:

```
Code
M2 ──────► ZRST M100, M200
```

Pressing stop button immediately clears all motion flags.

Section 4: Output Segment + Manual (Rungs 17-18)

Rung 17 - Motor UP (Y0):

The motor UP output is energized when:

Path 1 - Manual Mode UP:

```
Code
M7(NO) AND M0(NC) AND M5(NC) AND M6(NO) AND M3(NC) ──────► Y0
```

- Emergency bit active (normal state)
- Auto/Man = OFF (Manual mode via NC)
- Manual Up/Down = OFF (UP direction via NC)
- Inching bit active (jog button pressed)
- Up Sensor = OFF (not at upper limit via NC)

Path 2 - Auto Mode UP:

```
Code
M100(NO) ──────► Y0
```

- Auto UP flag is set

Rung 18 - Motor DOWN (Y1):

The motor DOWN output is energized when:

Path 1 - Manual Mode DOWN:

```
Code
M0(NC) AND M5(NC) AND M6(NO) AND M4(NC) ──────► Y1
```

- Auto/Man = OFF (Manual mode)
- Manual Up/Down = OFF (DOWN direction when M5 NC used differently)
- Inching bit active
- Down Sensor = OFF (not at lower limit)

Path 2 - Auto Mode DOWN:

```
Code
M200(NO) ──────► Y1
```

- Auto DOWN flag is set

A.7 Program Operation Summary

Table A.5: Operating Modes Summary

Mode	Condition	Operation
Auto Mode	M0 = 0 (X0 = OFF)	Continuous up/down cycling after Start pressed
Manual Mode	M0 = 1 (X0 = ON)	Jog operation with Inching button
Emergency Stop	M7 = 1 (X7 = ON)	All motion immediately stops

Table A.6: Auto Mode Sequence

Step	Condition	Action	Duration
1	Start button pressed	SET M100, Motor UP runs	Until upper limit
2	Upper limit reached (M3=1)	RST M100, SET M110	Immediate
3	Down delay active	Timer T1 running	0.1 seconds
4	T1 complete	SET M200, Motor DOWN runs	Until lower limit
5	Lower limit reached (M4=1)	RST M200, SET M120	Immediate
6	Loop delay active	Timer T0 running	0.1 seconds
7	T0 complete	Return to Step 1	Cycle repeats

Table A.7: Manual Mode Operation

Direction Switch (X5)	Inching Button (X6)	Result
OFF (M5=1 via NC)	Pressed	Motor moves UP
ON (M5=0)	Pressed	Motor moves DOWN
Any	Released	Motor stops

A.8 Safety Features Summary

Feature	Implementation	Rung	Description
Emergency Stop	ZRST M100, M200	9	Immediately clears all motion flags
Upper Limit Protection	ANI M3 in Y0 output	17	Prevents upward motion at limit
Lower Limit Protection	ANI M4 in Y1 output	18	Prevents downward motion at limit
Stop Button	ZRST M100, M200	16	Operator-initiated stop
Anti-Jogging Delay	T1 timer	12	Prevents immediate reversal
Direction Interlock	Separate M100/M200	10-14	Prevents simultaneous up/down

Appendix B: Component Datasheets (Excerpts)

B.1 Delta DVP-SS2 PLC Specifications

Parameter	Specification
Model	DVP-SS2
CPU Type	32-bit RISC
Program Capacity	8K Steps
Execution Speed	0.58 µs/instruction
Digital I/O	8 inputs, 6 outputs (base)
Expansion	Up to 256 I/O points
Power Supply	24V DC (+20%, -15%)
Current Consumption	500 mA max
Operating Temperature	0°C to 55°C
Storage Temperature	-25°C to 70°C
Humidity	5-95% RH (non-condensing)
Dimensions	90 × 86 × 60 mm
Weight	250 g
Certification	CE, UL

B.2 Inductive Proximity Sensor Specifications

Parameter	Specification
Model	LJ18A3-8-Z/BX
Detection Type	Inductive
Sensing Distance	8 mm
Target Material	Ferrous metal
Output Type	PNP, Normally Open
Operating Voltage	10-30V DC
Output Current	300 mA max
Response Frequency	500 Hz
Protection Rating	IP67
Housing Material	Brass, nickel-plated
Housing Diameter	18 mm
Body Length	55 mm
Connection	3-wire, 2m cable
Operating Temperature	-25°C to +70°C

B.3 SMPS Power Supply Specifications

Parameter	Specification
Model	S-120-24
Input Voltage	85-264V AC
Input Frequency	47-63 Hz
Output Voltage	24V DC (adjustable ±10%)
Output Current	5A continuous
Output Power	120W
Regulation	±1%
Ripple	<120mV p-p
Efficiency	>88%
Protection	OVP, OCP, SCP
Operating Temperature	-25°C to +70°C
Cooling	Convection
Dimensions	199 × 98 × 38 mm
Weight	450 g
Mounting	Screw or DIN rail

Appendix C: Bill of Materials

Complete Bill of Materials:

Item	Description	Part Number	Qty	Unit Price (₹)	Total (₹)
1	Delta PLC DVP-SS2	DVP14SS211T	1	28,500	28,500
2	SMPS 24V 5A	S-120-24	1	3,200	3,200
3	Relay Module 24VDC	MY2N-J-24VDC	2	2,350	4,700
4	Relay Socket	PYF08A	2	120	240
5	Proximity Sensor	LJ18A3-8-Z/BX	2	850	1,700
6	AC Motor 0.75kW	Y2-802-4	1	16,500	16,500
7	Contactor 12A	LC1D12	1	750	750
8	Overload Relay	LRD07	1	2,650	2,650
9	MCB 3P 16A	C60N-3P-16A	1	480	480
10	Zip Chain Actuator	ZA500-5	1	75,000	75,000
11	Start Button (Green)	XB2-BA31	1	100	100
12	Stop Button (Red)	XB2-BA42	1	100	100

Item	Description	Part Number	Qty	Unit Price (₹)	Total (₹)
13	E-Stop Mushroom	XB2-BS542	1	200	200
14	Selector Switch	XB2-BD21	1	150	150
15	Pilot Light Green	XB2-BV63	1	100	100
16	Pilot Light Red	XB2-BV64	1	100	100
17	Electrical Enclosure	AE-3040-15	1	4,665	4,665
18	DIN Rail 35mm	TH35-1M	1	180	180
19	Terminal Blocks	UK-2.5N	20	25	1000
20	Wire 1.5 sq mm	Assorted	30m	18	540
21	Wire 2.5 sq mm	Assorted	10m	28	280
22	Cable Gland PG11	PG11	6	35	210
23	Flexible Conduit 20mm	-	3m	85	255
24	Wire Ferrules	Assorted	100	2	200
25	Cable Ties	200mm	100	1	200
26	Miscellaneous Hardware	MS Tube 50×50×3,Plate	-	-	40,000

Item	Description	Part Number	Qty	Unit Price (₹)	Total (₹)
				Grand Total	1,82,000

Appendix D: Safety Compliance Checklist

Item	Requirement	Compliance	Notes
1	Emergency stop accessible	✓	Mounted on control panel
2	E-stop positive opening contacts	✓	XB2-BS542 certified
3	E-stop requires manual reset	✓	Twist-to-release type
4	Limit switches at travel extremes	✓	Inductive proximity sensors
5	Motor overload protection	✓	Thermal overload relay
6	Short circuit protection	✓	MCB installed
7	Proper grounding	✓	All metal parts bonded
8	Enclosure IP rating adequate	✓	IP55 enclosure used
9	Warning labels installed	✓	Voltage and pinch point labels
10	Lockout/tagout provisions	✓	Main disconnect lockable
11	Interlock prevents simultaneous up/down	✓	PLC logic implemented
12	Mechanical brake holds load	✓	Actuator includes brake

Item	Requirement	Compliance	Notes
13	Structural safety factor adequate	✓	>3:1 on all members
14	Pinch point guards installed	✓	Bellows covers scissor
15	Documentation complete	✓	O&M manual provided

Appendix E: Maintenance Schedule

Interval	Task	Details
Daily	Visual inspection	Check for unusual noise, vibration, or damage
Daily	Verify E-stop function	Test emergency stop operation
Weekly	Check sensor alignment	Verify sensors detect targets correctly
Weekly	Clean sensors	Wipe sensor faces to remove contamination
Monthly	Inspect electrical connections	Check for loose terminals
Monthly	Test limit function	Verify stop at upper and lower limits
Quarterly	Lubricate chain	Apply chain lubricant per manufacturer spec
Quarterly	Inspect mechanical components	Check pivots, rollers, and guides for wear
Annually	Comprehensive inspection	Detailed examination of all components
Annually	Calibration verification	Confirm position accuracy
As needed	Replace worn components	Per inspection findings

Appendix F: Troubleshooting Guide

Symptom	Possible Cause	Remedy
System does not start	No power	Check main supply, MCB
	E-stop activated	Release and reset E-stop
	PLC fault	Check PLC error indicators
Motor does not run	Contactor not pulling in	Check control circuit
	Overload tripped	Reset overload, check motor
	Wiring fault	Check motor connections
Lift does not rise	Forward relay not activating	Check relay, PLC output
	Top sensor activated	Check sensor, adjust if needed
	Mechanical obstruction	Inspect for binding
Lift does not lower	Reverse relay not activating	Check relay, PLC output
	Home sensor activated	Check sensor, adjust if needed
Lift stops mid-travel	Limit sensor misaligned	Realign sensor

Symptom	Possible Cause	Remedy
	Loose connection	Check wiring
	Motor overheating	Allow cooling, check load
Position inaccurate	Sensor position shifted	Readjust sensor mounting
	Sensor sensitivity incorrect	Adjust sensor potentiometer
Unusual noise	Insufficient lubrication	Lubricate chain mechanism
	Worn bearings	Inspect and replace
	Loose fasteners	Tighten all fasteners
Running indicator stays off	Lamp burned out	Replace indicator lamp
	Wiring fault	Check indicator circuit
